Introduction: Health improvement, control of communicable diseases and increase in life expectancy among the elderly of developed and developing countries has greatly increased. Since the health care and social needs of older adults differ from that of other adults, it is necessary to identify the needs of the elderly in order to make proper plans that will promote their health. The aim of this paper is to critically review these researches.

Methods: A comprehensive literature review on the needs assessment of elderly health was applied searching English and Persian databases in Pub Med, Science Direct, ProQuest, Elsevier, Magiran, ISC and using key words including, Health need, Assessment, Elderly, Aging, Older adults, Aged and Health care needs.

Results: Initial search yielded 745 references, considering the inclusion criteria, 21 papers were reviewed. Results revealed that in conducting needs assessment, various methods and procedures in various health dimensions including physical health, mental health, emotional, care, social, cultural, economic, nutritional, service, security, legal and educational needs have been utilized. Some of the dimensions had been more explored and some rarely.

Conclusion: Most of the conducted studies had mainly focused on the elderly physical health needs and had neglected to take in to account other needs such as social and health care needs. In order to comprehensively recognize the health needs of the elderly, identifying their health care and care services is also important. Furthermore, in addition to quantitative studies, discovering the older adults’ perceptions of their own health needs is also necessary. It seems that the challenge ahead of managers, experts and researchers on elderly health is trying to design comprehensive mechanisms of health need assessment and considering it as a reference for any future planning.

Keywords: Aged, Needs Assessment, Health, Review Literature as Topic

Introduction

Human’s longevity has increased due to advances in health and by controlling communicable diseases. Therefore, the number of elders is increasing in developed and developing countries (1, 2). In almost every country, the ratio of the population over 60 has grown more than any other age group (3). According to world health organization, the world is aging with a rapid pace in such a way that the ratio of people who are 60 and more in the world will double between 2000-2050; reaching to about 11 to 22 % (4). According to reports, 80% people over 65 years old suffer from at least one disorder or chronic disease (5-7) such as diabetes or cardiovascular diseases among elders, and as a result, these people need more health
care than other citizens of the society (8-9). Twenty three percent (23%) of the total global burden of disease is attributable to disorders in people aged 60 years and above (10). Furthermore, reduction of relationships and social interactions, due to reasons such as loss of wife/husband and relatives, poverty, and loneliness are common social issues which make them face a big challenge to maintain a healthy lifestyle (11). Currently, as well as developing appropriate and effective plans and strategies to solve these issues have become a global common concern. World health organization, considered supporting researches and trainings regarding the elderly and social cares as a basic principle in its new strategy for the year 2006-2015. After the Madrid-Spain statement, countries were obliged to provide elderly care and services in an extensive manner based on needs assessment of the physical and mental health of the elderly from 65 years old (12).

If we consider need as distance between existing situation and what must be, need may be categorized as “felt need” i.e. a need which is recognized by an individual or a society and “determined need”, i.e. need which is determined by experts. Some researchers suggest that both kind of needs should be addressed and preferably should not be very different (13-16).

Need assessment is a systematic study of difference between what exists and what must exist in considered groups and situations (17-19) to guide goals setting, and finally to determine priorities for action. From these perspectives, it can be considered as the first step in designing every program (20, 21). Health needs assessment is analyzing behavioral, environmental and physiological factors for health, even when existing health problems have not yet emerged (22).

Several countries and various researchers have assessed the health needs of the elderly. This paper tries to critically review the health needs of the elderly and also to assess these needs. To this end, it aims to provide a comprehensive description for various frameworks and tools employed in conducted studies, to determine the dimensions and ranges of the elderly health needs and also, identify researchers understanding of elderly health needs as well as its determinant factors.

Methods

Related studies, since 1990, were identified by searching English and Persian databases including, Pub Med, Science Direct, ProQuest, Elsevier, Magiran, and SCI, using key words; Health Needs, Needs assessment, Elderly, Ageing, Older adults, Aged and Health care needs. The primary inclusion criteria were (1) the full-text articles published either in English or Persian since 1990, (2) the organizational reports, (3) the studies on needs assessment of elderly (60 years old and more) and (4) the quantitative, qualitative or mixed method studies.

The process of identifying studies is show in Figure 1.

Figure 1. Process of identifying studies

Ethical considerations

This study was approved by the ethics committee of Shahid Beheshti University of Medicine Sciences with number SBMU.REC.1393.682.

Results

Among the 745 investigated references, 21 papers met the inclusion criteria. Table 1 shows a summary of the investigated papers.

Only two papers had taken into account the elders’ own points of view regarding their health and health care needs (23, 42) as majority of studies assessed health needs from specialist’s point of view. With respect to the research method, most of the studies took quantitative approach as only two papers applied qualitative approach (24, 25, 27-30, 32-35, 37, 38, 40), and, two studies used mixed method research approach (23, 42). While most of the studies were cross sectional studies, there were only one cohort studies and two review studies.

Applied tools in these studies were mainly researcher made tools and in some studies several tools were used for investigating health needs (36-41). For example, Katz and Lawton tools were utilized in some studies to investigate functional situation in physical health (39-41). In two studies, GDS tools were used for investigating mental health (30, 36). In a mixed method study, a comprehensive, standard tool was designed for assessing health needs in various dimensions for urban Tehran elders (26). Among these studies, only one of them used grounded theory approach and precede-proceed model (23).

As table shows, studies explored different dimension of elderly health had been focused. However, as Figure 2 shows physical health needs have been explored in majority of health needs assessment while some dimensions have rarely been explored.

![Figure 2. The most important needs were investigated in studies](image-url)
Few studies mentioned other dimensions such as urban services like appropriate transportation for the elderly and the urban physical environment problems (30, 31).

In terms of health needs identified in the elderly, the most important identified needs were social support (23), social isolation, the need for care outside the home to perform activities of daily living, end of life care, financial needs after retirement and the needs of urban services, needs of appropriate transportation (31).

In cross-sectional studies, some of which were performed by organizations and elderly departments or Ministry of health of various countries, different dimensions of health needs were investigated and in fact it dealt with analyzing gap in elderly health needs.

In physical health needs assessment, the most investigating issue was the prevalence of illnesses and disorders related to health, nutritional and functional situations. Major physical problems in elders were musculoskeletal disorders, cardiovascular disease, anxiety and stress, audio-visual disorders, and depression in most studies (Figure 3) (27-30, 32). It also dealt with needs assessment of health and nutrition knowledge among elders and health-care employees (25).

In studies performed on Iranian elders, major problems mentioned were skeletal-muscular problems, cardiovascular disease, and depression (Figure 4). Female elders suffer from more problems and disorders than male elders (33-35, 37, 38).

Discussion

Health needs assessment can be carried out from two points of view, from people's point of view or society and from experts' point of view. On the other hand, views about need can be internal or external which are not necessarily similar or conforming. A review of texts indicates that researchers and managers have conducted external research assessing the needs of the elderly according to the researchers' judgment utilizing different questionnaires. Rarely studies explored the needs from the point of view of the elderly which may be the best index for specifying his/her health situation (44).

When investigating different papers regarding elderly health needs, it was revealed that there were different aspects regarding the health needs of the elderly. Medical models often focus on physical dimension of health for determining elderly health need, while comprehensive approach deals with all dimensions of health and in particular emphasizes on the assessment of the social and environmental aspects. Some studies had focused on holistic approaches in assessing the needs of the elderly (31).

Meeting health needs and problems related to the older adults' health should not be viewed independently without considering several factors. A wide range of determining factors such as social factors (e.g. children's separation from parents and their isolation without any physical support for doing daily activities), maltreatment and insufficient treatments, little awareness about risk factors, nutritional needs, emotional and mental needs (such as social seclusion, spiritual stress, spare time problems), economical needs (reduction of financial sources, reduction of income due to retirement) all of these affect the fulfillment of basic needs such as adequate nutrition, clothing and housing (45-48). Furthermore, factors related to health-care system (in most countries lack of health insurance for the elderly, lack of insurance coverage, insufficient availability) also affect the fulfillment of health needs and consequently have a considerable influence on quality of elderly lives (49). Few of the conducted studies dealt with investigating all these factors and health care needs, social and civil services.

Another problem is lack of a comprehensive tool for assessing all dimensions of health need and related needs of the elderly health. Applying questionnaire to understand the health need of the elderly is faced with many important limitations and weaknesses. Existing tools limit the possibility of comparing elderly needs among different societies, as different conceptual frameworks and so different questionnaire have been used. In addition, as it was mentioned earlier, physical health needs has been explored in more details, perhaps for the reason that accurate assessment of physical health is easier than mental, spiritual, social health needs. Separating some non-physical dimensions of health is more difficult due to higher over lap and closer relationship. For example, hope is defined in some tools as mental health but in others it is defined as spiritual health (26, 41).
Review of studies and existing experiences show that dimension of physical health is assessed in most need assessment of the elderly while dimensions of mental, social and spiritual health are less explored though they are important. Among the above mentioned limitations, intrinsic limitation in the quantitative method of study in understanding the phenomenon should be also pointed. People’s understanding of their needs is mainly a cognitive phenomenon and elderly perceptions and experiences about their health needs lead to a better and more comprehensive understanding of health need and its dimensions. Qualitative procedures explain the background and situations in which people live and speak. Applying need assessment by qualitative method is faced with serious limitations such as generalizability and pre-judgment and personal comments of researcher in real life despite providing a comprehensive understanding of needs stated by the elderly. With attention to the importance of need assessment in planning and promoting elderly health, it is necessary to assess needs considering perspectives of, experts and elderly, family members and their careers to obtain a deeper, more comprehensive and generalizable understanding of elderly needs by removing limitations of need assessment through one approach and one research method. Utilizing both quantitative and qualitative research methods will help enriching the scope and depth of the assessments.

Because healthy aging requires conditions and factors using findings of needs assessment studies of the health and active aging framework of the World Health Organization(5), the most important aspects of the health needs of the elderly in the conceptual framework are outlined in Figure 5.

Figure 5. The conceptual framework of the elderly health need

Conclusion

In order to investigate health needs of the elderly in addition to physical health, attention to mental, social and economic needs, provided services by health care; social organization and physical urban environment are of great importance. Investigating health needs should not be limited to physical dimension. Investigation of need assessment in elders should be more focused on mental needs, as it is influenced by social, emotional interactions, functional and cognitive abilities and social support. It seems that manager and researchers of elderly health should try to design comprehensive mechanisms of need assessment and make it a reference for future planning. This mechanism should enjoy both qualitative and quantitative study methods and recognize understanding of experts and family members. Also, more attention should be given to assess and fulfill the social and economic needs of the elderly. Since current procedures do not consider health as goal of life but a means for life, satisfaction from quality of life should be given higher priority in the health of the elderly,. Enjoying happiness, respect and meaning in life even with sickness which is inevitable during last years of the elderly should be considered more by the society than just providing treatment services.

Study limitations

Not all databases were utilized in the present study and the search period was limited to the publication from 1990 onward.

Conflict of interest

Hereby, the authors confirm that they have no conflict of interest that might influence their work.

Acknowledgment

The present study was the research project report approved by school of public health, Shahid Beheshti University of Medical Sciences, and Geriatric Research Center of University of Social Welfare and Rehabilitation Sciences.
